

# fMRI Course, Day 12: Introduction to Open Science and BIDS

August 10<sup>th</sup>, 2023

# Review of Kriegeskorte Supplementary Material

# Questions

**What are three types of multiple comparisons correction?**

**What is the summary statistic approach?**

**What is an example of a circular analysis?**

**Why is it widely recommended to use a CDT of  $p=0.001$ ?**

# Questions

**What does permutation thresholding do for parametric (i.e., continuous) regressors?**

**What can we do to improve between-subjects inferences (brain-individual differences associations)?**

**Are mass univariate analyses potentially less appropriate than previously thought?**

**How to address large, contiguous, undifferentiated clusters, even after you have increased alpha to break them up?**

**Statistics:** *p-values adjusted for search volume*

**Reverse Normalization**

# Reverse Normalization of fMRI Data

May 13, 2017

The screenshot displays the AFNI (Analysis of Functional NeuroImages) software interface. At the top, the title bar reads "XQuartz Applications Edit Window Help". The main window title is "Reverse Normalization of fMRI Data".

The interface is divided into several panels:

- Left Panel:** Contains coordinate information: `[order: RAI=DICOM]`, `x = 6.000 mm [L]`, `y = -23.000 mm [A]`, `z = 22.000 mm [S]`. It also has options for "Xhairs" (Multi, X+), "Color" (green), "Gap" (5, Wrap), and "Index". Below are view options for Axial, Sagittal, and Coronal, each with "Image" and "Graph" buttons.
- Top-Right Panel:** "Original View" section with options for "AC-PC Aligned" and "Talairach View". It includes buttons for "Define Overlay ->", "See Overlay", "Define Datamode ->", "DataDir" (Switch, Read), "UnderLay", "EditEnv", "OverLay", "NIML+PO", and "Control Surface".
- Center Panel:** A vertical color scale from 0.0000 to 1.000. It features a "Clusterize" button, a "Setup ICorr" button, and a "\*NOT Ready\*" status. Below the scale are fields for "ULay", "OLay", and "Thr", each with a "#0 #0" value. There are also "autoRange" checkboxes and a "Rota" control.
- Right Panel:** A terminal window showing command history: `Andrew% ls`, `Andrew% afni`, and `64: Mar 29 2017 (Version AFNI_17.0.18)`. It also displays output: `Input file`, `arp_Demo/ => 2 datasets`, and `METHOD) is SIMPLEX`. At the bottom of the terminal, it says `,750 (11 million [mega]) bytes long!`
- Bottom Panel:** A video player showing three brain slices. The video title is "ALTRI VIDEO" and the progress bar shows `3:52 / 5:49`. The YouTube logo and "View" button are visible.

## AFNI Overview

### What is AFNI?

AFNI (Analysis of Functional NeuroImages) is a suite of programs designed to analyze fMRI data. Created in the mid-1990's by [Bob Cox](#), AFNI is now used by hundreds of imaging labs around the world.

The following tutorials will show you how to analyze a sample dataset with AFNI. You will begin by learning the fundamentals of fMRI preprocessing, and then proceed to create a model of your data with AFNI's 3dDeconvolve command. We will finish by learning about different types of group analyses, and how to do region of interest (ROI) analyses.

### Start to Finish Analysis with AFNI

- [Introduction to AFNI](#)
- [AFNI Tutorial #1: Downloading the Data](#)
- [AFNI Tutorial #2: The Flanker Experiment](#)
- [AFNI Tutorial #3: Looking at the Data](#)

- [Appendix A: Parametric Modulation in AFNI](#)

Docs » FreeSurfer Short Course

[Edit on GitHub](#)

## FreeSurfer Short Course

### Overview

FreeSurfer is a software package that enables you to analyze **structural MRI** images - in other words, you can use FreeSurfer to quantify the amount of grey matter and white matter in specific regions of the brain. You will also be able to calculate measurements such as the thickness, curvature, and volume of the different tissue types, and be able to correlate these with covariates; or, you can contrast these structural measurements between groups.

An example of a typical group-level map created by FreeSurfer. This is from a group-level contrast between two groups, with the red and blue colors indicating where there are differences in cortical thickness between the groups. Typically these results are depicted on inflated brains; darker grey represents sulci, and lighter grey represents gyri.

This course will show you how to download and install FreeSurfer, and how to analyze a dataset from start to finish. Along the way you'll learn the basic FreeSurfer vocabulary and how to do preprocessing, volume editing, and region of interest analysis.

### Start to Finish Analysis with FreeSurfer

## Karl Pearson (1904)

### REPORT ON CERTAIN ENTERIC FEVER INOCULATION STATISTICS.

PROVIDED BY LIEUTENANT-COLONEL R. J. S. SIMPSON, C.M.G.,  
R.A.M.C.

BY KARL PEARSON, F.R.S.,  
Professor of Applied Mathematics, University College, London.

The following table gives the results of calculating the correlation coefficients of the tables in Appendix B :

INOCULATION AGAINST ENTERIC FEVER:			
<i>Correlation between Immunity and Inoculation.</i>			
I. Hospital Staffs ...	...	+ 0.373	± 0.021
II. Ladysmith Garrison ...	...	+ 0.445	± 0.017
III. Methuen's Column ...	...	+ 0.191	± 0.026
IV. Single Regiments ...	...	+ 0.021	± 0.033
V. Army in India ...	...	+ 0.100	± 0.013
Mean value ...	...	+ 0.226	
<i>Correlation between Mortality and Inoculation.</i>			
VI. Hospital Staffs ...	...	+ 0.307	± 0.128
VII. Ladysmith Garrison ...	...	- 0.010	± 0.081
VIII. Single Regiments ...	...	+ 0.300	± 0.091
IX. Special Hospitals ...	...	+ 0.119	± 0.022
X. Various military Hospitals ...	...	+ 0.194	± 0.022
XI. Army in India ...	...	+ 0.248	± 0.030
Mean value ...	...	+ 0.193	

If we except IV and VII, the values of the correlations are at least twice (in the very sparse data of VI) and generally four, five, or more times their probable errors. From this standpoint we might say that they are all significant, but we are at once struck with the extreme irregularity and the lowness of the values reached. They are absolutely incomparable with the fairly steady and large values of the vaccination correlations obtained for different epidemics and towns. The effect of enteric inoculation is evidently largely influenced by difference of environment or of treatment.

For example, taking the relation between deaths and recoveries, and presence and absence of vaccination scar in cases of small-pox, we have :<sup>2</sup>

	Correlation.
Metropolitan Asylums Board Returns,	
Epidemic 1893 ...	0.595 ± 0.027
Epidemics for six towns ...	0.656 ± 0.009
Sheffield, 1887-8 ...	0.769 ± 0.012
Homerton and Fulham, 1873-85 ...	0.576 ± 0.009
London: Epidemic 1901 ...	0.578 ± 0.031
Glasgow: Epidemic 1900-1 ...	0.629 ± 0.030

We may safely say that the protective character of vaccination as against mortality after incurring small-pox is very substantial, and numerically it is represented by the value 0.6, which is fairly closely the actual result for the various epidemics which have at present been dealt with.

# How to use this?

**One option: BrainMap**

**Contains links to Sleuth and GingerALE software**

**Can also enter coordinates to see where other papers  
also report activation**

## Announcements

March 4, 2021: The BrainMap database is now back up after maintenance this morning. Thank you for your patience.

## What is BrainMap?

BrainMap is a database of published functional and structural neuroimaging experiments with coordinate-based results (x,y,z) in Talairach or MNI space. The goal of BrainMap is to develop [software](#) and [tools](#) to share neuroimaging results and enable meta-analysis of studies of human brain function and structure in healthy and diseased subjects.

The BrainMap Project is developed at the [Research Imaging Institute](#) of the [University of Texas Health Science Center San Antonio](#). BrainMap was conceived in 1988 and originally developed as a web-based interface. After more than 20 years of development, BrainMap has evolved into a much broader project whose software and data have been utilized in numerous [publications](#). BrainMap provides not only data for meta-analyses and data mining, but also distributes software and concepts for quantitative integration of neuroimaging data.

## Collaborations

The BrainMap development team welcomes [collaborations](#). We will provide guidance and assistance in the execution of meta-analyses upon request. We encourage collaborations that develop new tools for meta-analysis or use BrainMap data to develop or validate other neuroinformatics tools and strategies.

## BrainMap ICA Results

Networks resulting from an ICA decomposition of modeled activation images archived in BrainMap strongly correspond to resting state networks, as shown by [Smith et al., 2009](#). Given the vast amount of metadata archived in BrainMap, the functional significance of these intrinsic connectivity networks was quantitatively assessed by [Laird et al. \(2011\)](#). For more details, and the associated network images and metadata at a model order of 20, please click [here](#).

## Citing BrainMap

If you have used the BrainMap database in your research, please cite one or more of the following papers in your references.

For citations concerning Sleuth, Scribe, and BrainMap meta-data:

# GingerALE

**You can also create contrast maps to visualize the overlap and divergence of two meta-analyses**

**Requires performing two separate ALE analyses, as well as a pooled analysis (i.e., merging the two)**

# GingerALE

The screenshot shows the GingerALE software interface. At the top, there is a title bar with the text "GingerALE" and a logo. Below the title bar, the main window is divided into several sections:

- Input Data:** This section contains radio buttons for "Single Study" and "Contrast Studies" (which is selected). Below this are text input fields for "Coordinate System" (MNI), "Data Set 1" (L\_insula\_ALE\_pN001), "Data Set 2" (R\_insula\_ALE\_pN001), and "Pooled Data Sets" (LR\_insula\_ALE\_pN01). Each data set field is followed by a summary of its parameters: "1634 Foci, 93 Experiments, 51560 mm<sup>3</sup>" for Data Set 1, "1392 Foci, 78 Experiments, 32376 mm<sup>3</sup>" for Data Set 2, and "2743 Foci, 156 Experiments, 107984 mm<sup>3</sup>" for Pooled Data Sets.
- Settings:** This section includes a "FDR pN" field with a dropdown arrow and a value of 0.05, a "P Value Permutations" field with a value of 5000, and a "Min. Volume (mm<sup>3</sup>)" field with a value of 0.
- Output Files:** This section contains two text input fields: "Data Set 1 Output Name" (L\_insula) and "Data Set 2 Output Name" (R\_insula).

At the bottom of the interface, there is a status bar with the text "Ready..." and a "Compute" button.

# GingerALE

**Advantages: Helps build intuition about how meta-analyses are conducted**

**Disadvantages: Can be tedious, even with auxiliary software (e.g., Sleuth)**

**Is there any way to automate this?**

# Reverse Inference

# Wager et al. Rebuttal

Lieberman and Eisenberger's (1) conclusions are based on [Neurosynth.org](http://Neurosynth.org) (7), a database of activation coordinates and words used in >11,000 neuroimaging studies. The claim of pain selectivity is based on a statistical preference in dACC activation studies for the use of pain-related words, compared with a modest number of alternatives (e.g., "salience"). Neurosynth analyses are based on word frequencies in published papers. They may not reflect the actual processes studied, and are not linked specifically to particular brain locations. They are subject to biases in how different literatures use words and label brain areas (e.g., "salience" has multiple meanings, and dACC is also called anterior mid-cingulate cortex). Neurosynth is useful for exploring structure-to-function mappings across a large literature, but it cannot provide definitive inferences about specific brain regions.

# Lieberman et al. Response

# Thoughts?

**What about a within-subjects study comparing pain and cognitive effects?**

**This should be the preferred method for making region-specific claims**

# Reproducing Results from Psychology Studies

## Present Day

### RESEARCH ARTICLE

## Estimating the reproducibility of psychological science

Open Science Collaboration<sup>\*†</sup>

+ See all authors and affiliations

Science 28 Aug 2015:  
Vol. 349, Issue 6251, aac4716  
DOI: 10.1126/science.aac4716

## This should be great, right?

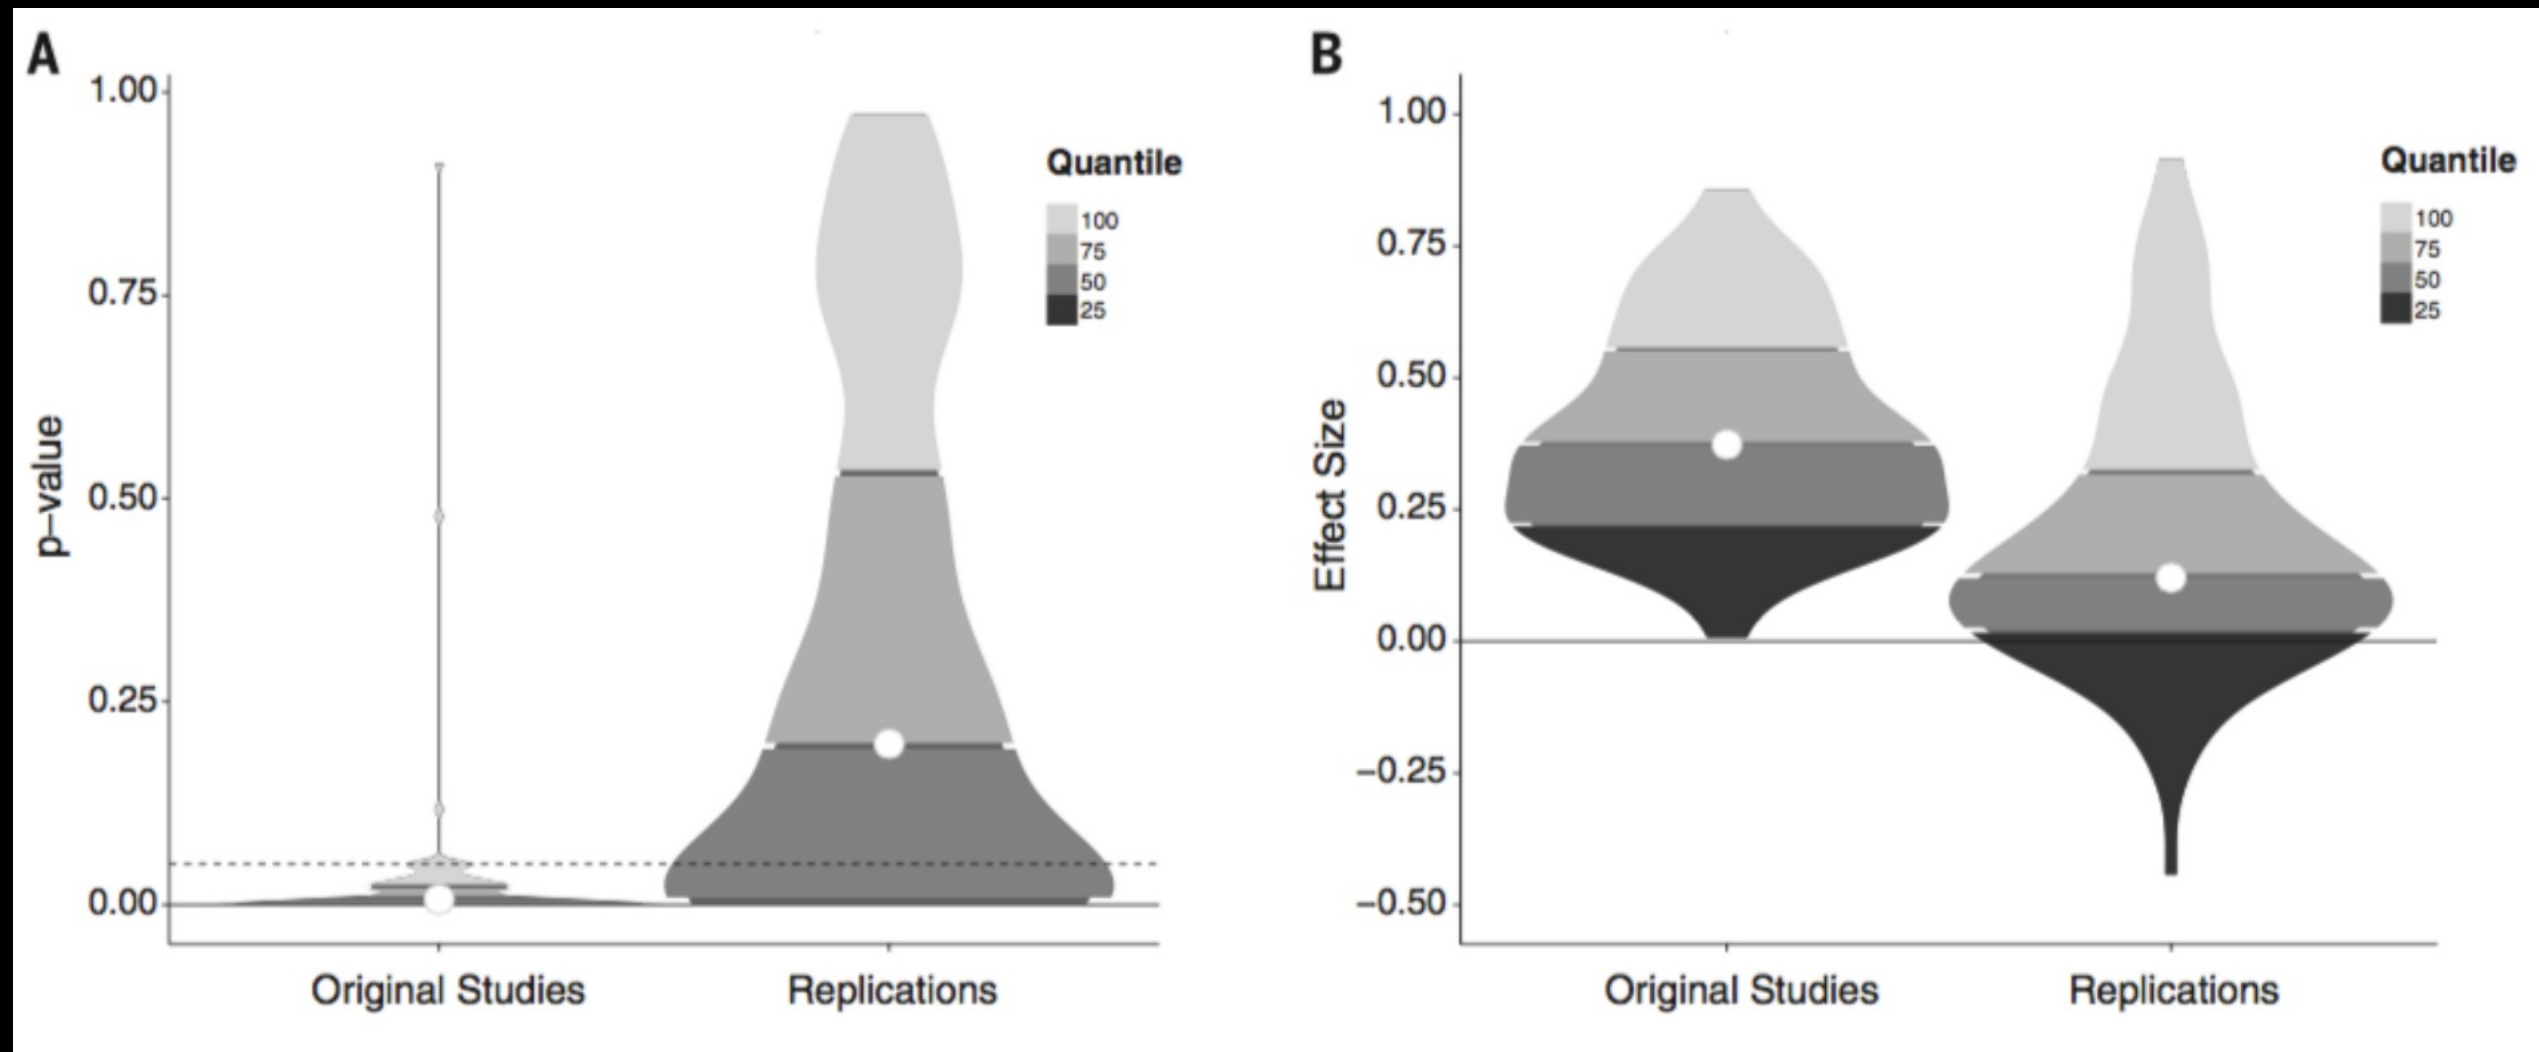

### RESULTS

We conducted replications of 100 experimental and correlational studies published in three psychology journals using high-powered designs and original materials when available. There is no single standard for evaluating replication success. Here, we evaluated reproducibility using significance and  $P$  values, effect sizes, subjective assessments of replication teams, and meta-analysis of effect sizes. The mean effect size ( $r$ ) of the replication effects ( $M_r = 0.197$ ,  $SD = 0.257$ ) was half the magnitude of the mean effect size of the original effects ( $M_r = 0.403$ ,  $SD = 0.188$ ), representing a substantial decline. Ninety-seven percent of original studies had significant results ( $P < .05$ ). Thirty-six percent of replications had significant results; 47% of

# Reproducing Results from Psychology Studies

# Reproducing Results from Psychology Studies

Why does this happen?

We discussed some of this on Tuesday  
(circular analyses, file-drawer problem, etc.)

Another issue is “p-hacking”, trying to obtain a significant result by continuing to run analyses

## Why Most Published Research Findings Are False

John P. A. Ioannidis

Published: August 30, 2005 • <https://doi.org/10.1371/journal.pmed.0020124>

**Like we discussed previously, controlling for Type I Error rates isn't enough to guarantee that results are real**

## **John Ioannides' 2005 Paper**

**The crux of the paper rests on a formula called  
Positive Predictive Value (PPV)**

**PPV is the number of true positives, divided by  
the number of rejected tests**

## John Ioannides' 2005 Paper

Let  $R$  be the ratio of the number of “true relationships” to “no relationships” (i.e.,  $\#H_A/\#H_0$ )

Let  $\alpha$ =alpha level, and  $(1-\beta)$ =Power

$$PPV = \frac{R(1 - \beta)}{\alpha + R(1 - \beta)}$$

A

B

C

— n=1 — n=5 — n=10 — n=50

## John Ioannides' 2005 Paper

Lastly, let  $u$ =bias, the amount that a study is affected by biased practices (e.g., p-hacking); anything that tends to generate a positive results when it shouldn't

A

B

C

— u=0.05 — u=0.20 — u=0.50 — u=0.80

**Table 4.** PPV of Research Findings for Various Combinations of Power ( $1 - \beta$ ), Ratio of True to Not-True Relationships ( $R$ ), and Bias ( $u$ )

$1 - \beta$	$R$	$u$	Practical Example	PPV
0.80	1:1	0.10	Adequately powered RCT with little bias and 1:1 pre-study odds	0.85
0.95	2:1	0.30	Confirmatory meta-analysis of good-quality RCTs	0.85
0.80	1:3	0.40	Meta-analysis of small inconclusive studies	0.41
0.20	1:5	0.20	Underpowered, but well-performed phase I/II RCT	0.23
0.20	1:5	0.80	Underpowered, poorly performed phase I/II RCT	0.17
0.80	1:10	0.30	Adequately powered exploratory epidemiological study	0.20
0.20	1:10	0.30	Underpowered exploratory epidemiological study	0.12
0.20	1:1,000	0.80	Discovery-oriented exploratory research with massive testing	0.0010
0.20	1:1,000	0.20	As in previous example, but with more limited bias (more standardized)	0.0015

# Corollaries

# What can be done?

**Follow COBIDAS guidelines (Nichols et al., 2016)**

**Run appropriate power analyses (discussed on Monday)**

**Pre-register your experiment (to be discussed on Friday)**

**Standardize your analyses (to be discussed right now!)**

**Questions?**

# Brief Overview of Python

# Growth of major programming languages

Based on Stack Overflow question views in World Bank high-income countries

# Advantages of Python

**Popular, lots of support (e.g., Stack Overflow)**

**Intuitive Syntax**

**Widely used for open-source projects, and especially  
for the latest neuroimaging methods**

**Easy to transfer code through Jupyter notebooks**

# Python Terms

Similar to Matlab terms (variables, conditional statements, etc.)

Dictionaries, tuples, and sets are used to store data

Different packages can be downloaded to perform  
different functions

```
from nlttools.data import Brain_Data
amygdala_mask = Brain_Data('https://neurovault.org/media/images/1290/FSL_BAmyg_thr0.nii')
view_img(amygdala_mask, data)
```

We can also plot a glass brain which allows us to see through the brain from different slice orientations. In this example, we will plot the binary amygdala mask.

```
plot_glass_brain(amygdala_mask)
```

```
<nilearn.plotting.displays.OrthoProjector at 0x7fad29aa88d0>
```

```

# How to convert to BIDS?

## Stanford Center for Reproducible Neuroscience

### BIDS Tutorial Series: Introductory Walkthrough

 February 22, 2018

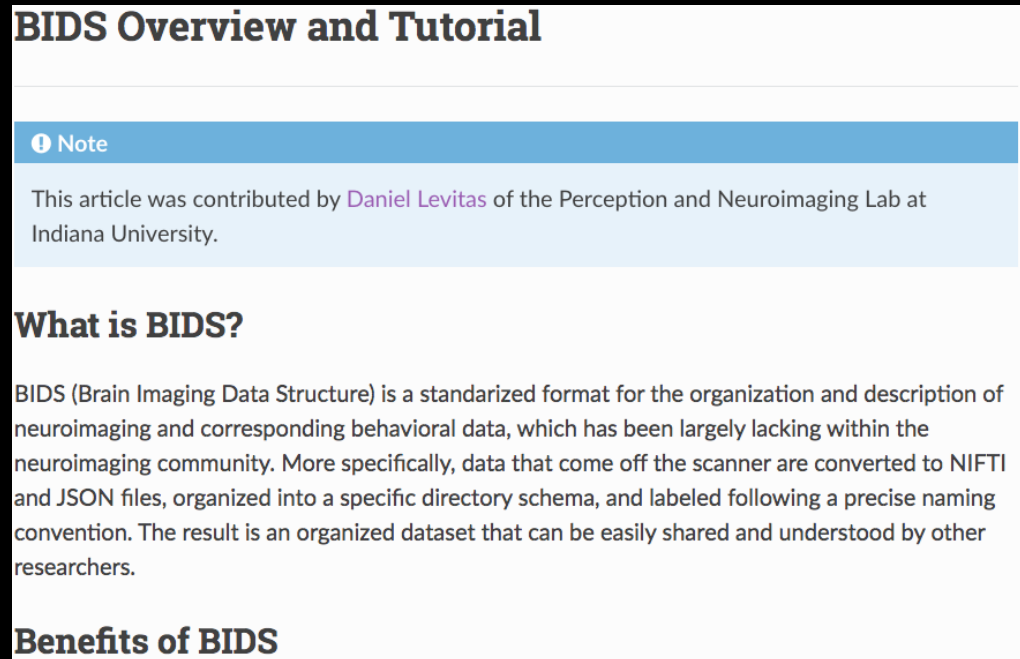

#### Introduction

Welcome to part 1A of the tutorial series “Getting Started with BIDS”. The tutorial series will introduce you to converting brain data into the BIDS organizational standard, provide an example of how to convert a dataset into BIDS (manually and an automated solution), and examine different off-the-shelf automated solutions. This tutorial will show a detailed step-by-step organizational guide to convert DICOMs into a BIDS validated dataset. The step-by-step guide will iteratively add one modality at a time until the full dataset is organized and validated. Even though performing the conversation manually is not expected we show it here for educational purposes. An automated solution is strongly recommended. An automated custom solution is discussed in the [next part of the tutorial series](#). Throughout this tutorial series portion, we will be using DICOMs from the [Nathan Kline Institute \(NKI\) Rockland Sample – Multiband Imaging Test-Retest Pilot Dataset](#). We will be following the specifications described in the [BIDS Specification version 1.0.2](#). If you are running into issues, please post your questions on [NeuroStars](#) with the bids tag. The next parts of this tutorial series will examine an automated custom solution and off-the-shelf solutions to consider using to convert your dataset into the BIDS standard.

# How to convert to BIDS?

A screenshot of a webpage titled "BIDS Overview and Tutorial". The page has a white background with a blue header bar. Below the header, there is a blue bar with a white circle containing an exclamation mark and the word "Note". The text below the note states: "This article was contributed by Daniel Levitas of the Perception and Neuroimaging Lab at Indiana University." Below this, there is a section titled "What is BIDS?" followed by a paragraph explaining that BIDS (Brain Imaging Data Structure) is a standardized format for neuroimaging and behavioral data, converted to NIFTI and JSON files. At the bottom of the screenshot, the section "Benefits of BIDS" is partially visible.

**BIDS Overview and Tutorial**

**Note**

This article was contributed by [Daniel Levitas](#) of the Perception and Neuroimaging Lab at Indiana University.

**What is BIDS?**

BIDS (Brain Imaging Data Structure) is a standardized format for the organization and description of neuroimaging and corresponding behavioral data, which has been largely lacking within the neuroimaging community. More specifically, data that come off the scanner are converted to NIFTI and JSON files, organized into a specific directory schema, and labeled following a precise naming convention. The result is an organized dataset that can be easily shared and understood by other researchers.

**Benefits of BIDS**

Requires certain commands (pigz, dcm2bids, etc.)

Should work with most Macintosh and Unix operating systems

## Variability in the analysis of a single neuroimaging dataset by many teams

Rotem Botvinik-Nezer, Felix Holzmeister, [...] Tom Schonberg [✉](#)

*Nature* 582, 84–88(2020) | [Cite this article](#)

### Abstract

Data analysis workflows in many scientific domains have become increasingly complex and flexible. Here we assess the effect of this flexibility on the results of functional magnetic resonance imaging by asking 70 independent teams to analyse the same dataset, testing the same 9 ex-ante hypotheses<sup>1</sup>. The flexibility of analytical approaches is exemplified by the fact that no two teams chose identical workflows to analyse the data. This flexibility resulted in sizeable variation in the results of hypothesis tests, even for teams whose statistical maps were highly correlated at intermediate stages of the analysis pipeline. Variation in reported results was related to several aspects of analysis methodology. **Notably, a meta-analytical approach that aggregated information across teams yielded a significant consensus in activated regions. Furthermore, prediction markets of researchers in the field revealed an overestimation of the likelihood of significant findings,** even by researchers with direct knowledge of the dataset<sup>2,3,4,5</sup>. Our findings show that analytical flexibility can have substantial effects on scientific conclusions, and identify factors that may be related to variability in the analysis of functional magnetic resonance imaging. The results

# fMRIPrep with other software (e.g., CONN)

The screenshot displays the CONN functional connectivity toolbox (version 20.1b) interface. The main window is divided into four stages: *SETUP*, *DENOISING (1st-level)*, *ANALYSES (1st-level)*, and *RESULTS (2nd-level)*. The *SETUP* stage is currently active. A 'Tools' menu is open, showing options: 'Open', 'Open Recent', 'New (blank)', 'New (import)', 'Save', 'Save As', and 'Close'. The 'New (import)' sub-menu is expanded, listing four options: 'from DICOM data files', 'from SPM design files', 'from BIDS dataset', and 'from fMRIPrep dataset'. The 'from fMRIPrep dataset' option is highlighted. Below the menu, there are 'New' and 'Open' buttons and a 2x2 grid of brain connectivity diagrams. At the bottom, a status bar indicates: 'Imports Setup information and functional/anatomical data from FMRIprep-preprocessed dataset storage: 470.1Gb available (24%)'. Logos for MIT and BU are visible in the bottom right corner.
